Subglacial Control on Glacier Flow in Northern Greenland

Beáta Csathó (University at Buffalo, SUNY, Buffalo, NY), C.J. van der Veen (U. of Kansas, Lawrence, KS) Ralph van Frese and Tim Leftwich (The Ohio State University, Columbus, OH), Janos Kiss (ELGI, Hungary), Hyung Rae Kim (NASA/GSFC, Greenbelt, MD) and Alex Braun (U. of Calgary, Canada)
Overview

- **Objective:** understanding the causes of unusual surface features and subglacial topography in NW Greenland.

- **Methodology and results:**
  - (1) Mapping shape and distribution of ice sheet features, basal valleys and subglacial hills
  - (2) Estimating crustal thickness from free-air gravity anomaly
  - (3) Reviewing other clues of geothermal conditions and bedrock geology
  - (3) Mapping bedrock lithology from gravity and magnetic field data

- **Conclusions and future work**
Greenland Ice Sheet, NW Greenland

- Major outlet glaciers: Humboldt (33), Peterman (1), Ryder (2)
- Mass balance and glacial dynamics:
  - The region is close to being in balance and have relatively small accumulation, BUT
  - Very large subglacial melt is measured under the floating tongue of Peterman Glacier
  - A mini-surge has been observed by InSAR over Ryder Glacier
  - Ice piracy is suggested between Humboldt and Peterman

→ Complex and active subglacial hydrologic system!!

Ice velocities from RADARSAT-1 data, 2000 (Rignot and Kanagaratnam, 2006)
Surface Features in NW Greenland

Shaded relief DEM from photoclinometry, SAR and ICESat altimetry

(1) Onset of Peterman Glacier
(2) Sinuous surface depression and bedrock channel E of Peterman Glacier was interpreted as an interconnected system of subglacial lakes or water transportation (Ekholm et al., 1998)
(3) Surface features with oblique angles to current flow over Humboldt Glacier
(4) Surface depressions over higher part of Humboldt and Peterman glaciers
(5) Subglacial hills within (1) and (4) (Legarsky et al., 1998)

Reykjavik, Iceland       June 19-23, 2006
Along Peterman Glacier

50 km
Distribution of Subglacial “Hills”

North: features are aligned along western boundary of the Peterman onset region

South: features are located in a region where ice flow direction might switch between Humboldt and Peterman Glaciers

Note:
(1) there could be unmapped features
(2) some features might mark elongated ridges
Subglacial Hills over the Onset Region of Peterman Glacier
Bedrock Geology, Geothermal Conditions

- **Subglacial geology:**
  - Lower Paleozoic Franklinian sedimentary basin in NW and NE
  - Reworked Proterozoic crystalline rocks, outcropping in Victoria Fjord in the middle
  - A large magmatic province, detected by aerogeophysical surveys in central and northern Greenland

- **Subglacial volcanism:**
  - Glacial volcanic erratics, NOT occurring in outcrops in N Greenland, has been described by Dawes et al., 2000

- **Geothermal heatflux:**
  - High and spatially variable geothermal flux is estimated at NGRIP (e.g. NGICP members, 2004)
  - Lithospheric thinning and crustal thermal erosion might be related to the Icelandic hotspot track
Map of major structural-stratigraphical units of Northern Greenland

Comparison of Crustal Thickness and Indication of High Geothermal Heatflux

Crustal thickness Computed from Free-Air Gravity Anomalies (Braun et al., submitted)

Subglacial melt mapped from Internal layer thickness (Fahnestock, personal com.)
Total Field Magnetic Map (nT)

Data from Verhoef et al., 1996
Free-Air Gravity Anomaly Map (mgal)

Data from J. Brozena and R. Forsberg
Conclusions

- Glacial-geological conditions in NW Greenland are similar to those observed on WAIS, since NW Greenland is characterized by thin crust, a large sedimentary basement, high and spatially variable geothermal heat flux, large magnetic anomalies and a complex hydrological system.

- Bedrock geology controls the southern extent of Humboldt glacier and possibly the onset of streaming flow on Peterman Glacier.
Conclusions (cont)

- Bedrock hills are interpreted as volcanoes, possibly erupted subglacially.
- Elongated subglacial depressions are interpreted as tunnel valleys created by sudden release of melt water, selective linear erosion (Humboldt) and active glacier erosion (curvilinear feature E of Peterman).
- Subglacial volcanic activity could contribute to important glacial dynamic processes, such as mini-surges of Ryder Glacier and observed high melt rate of the floating tongue of Peterman Glacier and therefore it has important implications for the mass balance and stability of the ice sheet.
- Future work: a lot …..
